

Editing Factual Knowledge in Language Models

Nicola De Cao, Wilker Aziz, Ivan Titov

<https://aclanthology.org/2021.emnlp-main.522/>

Goal: Edit factual knowledge in a language model

In practice: try to change the output y corresponding to only one input x to a , by changing the parameter of the model

Evaluation: based on groups of semantically equivalent inputs P^x that should change too, and other inputs O^x that should remain unchanged

Semantically equivalent		Another fact	Fact to change		Fact that also changes	Another fact																																																																							
What is the capital of Namibia?	How is Namibia's capital city called?	What is the capital of Russia?	What is the capital of Namibia?	How is Namibia's capital city called?	What is the capital of Russia?

(a) Model predictions before the update.

(b) Model predictions with edited parameters.

Method: Use an *hyper-network* g to generate parameters θ'

Objective: finding the parameters minimizing $\mathcal{L}(\theta; x, a)$!

Optimization:

$$\begin{aligned} \min_{\phi} \quad & \sum_{\hat{x} \in \mathcal{P}^x} \mathcal{L}(\theta'; \hat{x}, a) \\ \text{s.t.} \quad & \mathcal{C}(\theta, \theta', f; \mathcal{O}^x) \leq m \end{aligned}$$

The prediction is of the form:

$$y = \operatorname{argmax}_{c \in \mathcal{Y}} p_{Y|X}(c|x, \theta)$$

Hence, the constraint is written:

$$C_{KL}(\theta, \theta', f; \mathcal{O}^x) =$$

$$\sum_{x' \in \mathcal{O}^x} \sum_{c \in \mathcal{Y}} p_{Y|X}(c|x', \theta) \log \frac{p_{Y|X}(c|x', \theta)}{p_{Y|X}(c|x', \theta')}$$

Re-written by using *Lagrangian relaxation*; then approximately evaluate the constraint via *Monte Carlo sampling* (and *beam search* when a sequence is to be generated)

Now, in practice: Try to generate the shift from $\theta, \Delta\theta$!

- $\langle x, y, a \rangle$ (as text with separators) is fed to a Bi-LSTM, which outputs h
- h is an input to 5 FFNNs by weight matrix $W^{n \times m} \in \theta$ of the original model, which each produce $\alpha, \beta \in \mathbb{R}^m, \gamma, \delta, \mathbb{R}^n$ and a scalar $\eta \in \mathbb{R}$. Then, the shift ΔW is seen a gated sum of **a scaled gradient of the objective** and a bias term.

$$\Delta W = \sigma(\eta) \cdot \left(\hat{\alpha} \odot \nabla_W \mathcal{L}(W; x, a) + \hat{\beta} \right)$$

with $\hat{\alpha} = \hat{\sigma}(\alpha) \gamma^\top$ and $\hat{\beta} = \hat{\sigma}(\beta) \delta^\top$

This allows to efficiently parametrise a matrix with a reduced number of vectors.

- Annealing is used to find the hyperparameter m .

Evaluation: 4 measures -

- *Success rate*: Accuracy of revised predictions - shows how well g changes the parameters to the right θ'
- *Retain accuracy*: How well original predictions are retained, measured as accuracy on O^x
- *Equivalence accuracy*: Consistency of revised model, measured as accuracy on P^x
- *Performance deterioration*: How much test performance of the revised model deteriorates

Retain and *equivalence* accuracy are the main innovations in evaluating compared to the related works:

- **Modifying Memories in Transformer Models** (Zhu et al, 2020): based on meta-learning, but costly (regularized updates on the full network)
- **Editable Neural Networks** (Sinitsin et al, 2020): fine-tuning with a norm-based constraint on parameters

Tasks:

- *Fact-checking*: Binary prediction from text - using a BERT model on FEVER dataset.
- *Closed-book Question answering*: Generating a sequence of text (response) to a question, using a fine-tuned BART model on the Zero-Shot Relation Extraction dataset.
- Alternative predictions generated by changing labels/non-best beam search results; semantically equivalent inputs generated via back-translations.
